### **Eye and Orbit Ultrasound: Purpose, Procedure, and Risks**

Your eye is numbed with medicine (anesthetic drops). The ultrasound wand (transducer) is placed against the front surface of the eye. The ultrasound uses high-frequency sound waves that travel through the eye. Reflections (echoes) of the sound waves form a picture of the structure of the eye. The test takes about 15 minutes.

Ultrasound was first used in ophthalmology in 1936 by two American ophthalmologists. Mundt and Hughes." Using time amplitude-niude (A-scup) to evaluate an intraocular rumor, they showed that ultrasound had potential as a di-agnostic moil in ophthalmology. Soon afterward. Oksala and associates, in Finland, greatly expanded the use of A-scan for the diagnosis of intraocular disorders' and published data regarding the sound velocities of various components of the eye." In 1958, Baum and ...

An ultrasound of an eye in A-scan mode allows one-dimensional image of eye structures to be obtained. A-scan is used to measure various anatomical parameters of the eyeball structures (ultrasonic eye biometry) and as a review ultrasound. What A-scan is used for: A-scan is aimed at detecting foreign bodies of the eye;

The eye ultrasound is an imaging technique that uses high-frequency sound waves, similar to sonar, used in oceanography. Ocular ultrasound is most commonly used to measure the eye's axial length prior to cataract surgery. This measurement helps the cataract surgeon determine the best intraocular lens power and type for that particular eye.

Color Doppler imaging is a non-invasive ultrasound procedure which permits simultaneous gray scale imaging of structure and color-coded imaging of blood velocity. This improved technique allows the user to identify even very small blood vessels, such as those supplying the eye, from which measures of blood velocity and vascular resistance can be obtained. In the past five years, color Doppler imaging has found a number of applications in ophthalmology. A common examination procedure and ...

Ultrasonography (US) is, quite often, the first imaging modality used in eye and orbit assessment. The indications of oph- thalamic US cover a wide range of disease where direct clinical assessment is impossible or of little value. Doppler US enhances the ability to assess blood flow in the main arteries and veins.

### **Ultrasonography of the eye and orbit**

The superficial location of the eye, its cystic composition, and the advent of high-frequency ultrasound make sonography ideal for imaging the eye [].MRI is favored by radiologists, so there are few reports on ocular sonography in the radiology literature [2, 3].Sonography is used more commonly by ophthalmologists to evaluate the eye, particularly when direct examination by slit-lamp and ...

Ultrasound of the eye allows you to identify the slightest irregularities in the state of the eyeball, to evaluate the work of the muscles and blood vessels. This research method is the most informative and safe. With the advent of the ultrasound method, it has become much easier to make a diagnosis.

Emergency ocular ultrasonography is performed using a closed-eye technique. A large amount of standard water-soluble ultrasound transmission gel should be applied to the patient's closed eyelid so that the transducer doesn't have to touch the eyelid. Ultrasound gel is not detrimental to eye.

### **Ocular ultrasound - ACEP**

Ocular ultrasound, also known as ocular echography, "echo," or a B-scan, is a quick, non-invasive test routinely used in clinical practice to assess the structural integrity and pathology of the eye.

An eye ultrasound scan uses a small instrument called a probe. The sonographer puts clear gel over your closed eyelids and moves the probe gently over them. Sometimes the sonographer puts the probe directly over the surface of your eyes (the conjunctiva). For this you may have local anaesthetic drops put into your eyes.
